State: <u>Georgia</u> Grant Number: <u>08-953</u> Study Number: <u>6</u>

LONG RANGE PERFORMANCE REPORT

Grant Title:	State Funded Wildlife Survey						
Period Covered:	July 1	, 2010 - June 30, 2011					
Study Title:	Wild Turkey Production and Population Indices						
Study Objectives:	1.	To determine annually an index of statewide turkey populations and production success in Georgia.					
	2.	To organize data obtained in a form so that it can be used in sound management of turkeys in Georgia.					

Abstract

Twenty-nine percent more Poults+Hens were observed in 2010 (4,800) versus 2009 (3,709), compared to the same value for harvest season population index (Hours Hunted/Turkey Seen) in 2011 (1.7) as 2010 (1.7), and the exact same as what was predicted. An inverse correlation coefficient of r = -0.90 was obtained between the new production index and population indices for the entire survey period which began in 1978. Hunter success (67.4%) was similar to past seasons (2010 = 67.3%, 2009 = 64.3% and 2008 = 66.8%). The average number of poults per hen was 1.9, which was up 76% from 2009 (which was tied with 2007 for the worst season ever).

- A. Activity:
 - Job A. <u>Turkey Production Index Survey</u> This survey was conducted during the months of May through August from 1978 to 1991. Beginning in 1991, the survey period was shortened to June through August when statistical analysis of data indicated the shorter time period was adequate.

Cooperators involved in data collection for this survey were field personnel of the Game Management Section, Fisheries Management Section, Non-Game Section, and Law Enforcement Section of the Wildlife Resources Division. We have also obtained cooperators from the Georgia Forestry Commission. Observations were made during the course of regular field duties. No special efforts were made to locate turkeys for the survey.

Records were maintained of all turkey broods and hens, with and without broods. Data were compiled on a statewide and physiographic region basis. Historically, the average number of poults seen per observer was the best index of production, however, recent analysis indicated this was not the case with data between 1987-2006.

Currently, the best index of production data is estimated Total Poults+Hens.

Job B. Turkey Hunting Population Index Survey -

The hunter cooperators participating in the survey were obtained from names of prospects submitted by WRD personnel and current cooperators. Cooperators were also solicited through newspaper and magazine requests and programs to interest groups. Starting in 1990, randomly selected members of the Georgia Chapter of the National Wild Turkey Federation also were contacted to bring the total potential cooperating hunters to 2,000.

This survey is conducted during the regular spring gobbler-hunting season, which begins the first Saturday after March 19 and ends May 15. Specific information requested about each hunting trip was the date, hours hunted, county or physiographic region hunted, the number of turkeys seen, and the number of gobblers heard. Kill information was also requested, but was an optional item. Hunt record forms were supplied to all cooperators.

The number of turkeys observed per unit of hunting effort is used as an index of the hunting season population. The correlation between the population indices and the production indices are used in evaluating annual production and populations and in making comparisons for trends. Data were calculated on a statewide and physiographic region basis.

B. Target Date for Achievement and Accomplishments:

Job A. Planned dates and dates of accomplishment coincide, November 2, 2010.

Job B. Planned dates and dates of accomplishment coincide, August 31, 2011.

C. Significant Deviations:

Job A. None

Job B. None

- D. Finds:
 - Job A. In 2010, 356 broods were observed (Table 1). This total is more than in 2009 (308 broods were observed), the best since 2006 and 8% greater than the 5-year average (330, 2005-09). The average brood size for 2010 was 8.9 poults 41% more than the 2009 average of 6.3, and 6% greater than the 5-year average (8.4). Twenty-nine percent more Poults+Hens were observed in 2010 (4,800) versus 2009 (3.709; Table 6), and 5% greater than the 5-year average (4,570). The total number of poults observed/estimated was 3,164 and was 63% more than 2009 (1,943), and 15% greater than the 5-year average (2,748).

Examination of poults/observer revealed that statewide it too was more by 82% for 2010 (16.4) compared to 2009 (9; Table 3), and 29% greater than the 5-year average (12.76). Poults/observer was up in all physiographic regions from 2009 except for Ridge and Valley (decreased by 35%). The index for Upper and Lower Coastal Plain (UCP [IV] and LCP [V]) increased greater than 78 % from 2009. Piedmont (III) and Blue Ridge mountains (II) were up greater than 23% over 2009.

The number of hens reported totaled 1,636 (Table 4) and was down 10% from the 5year average (1,821). The percent of hens with poults (46%) was 34% more than the 2009 (Table 5) and 18% greater than the 5-year average (39%). The average number of poults per hen, 1.9, increased by 76% from 2009 and 27% greater than the 5-year average (1.5) and therefore production was considered fair for 2010. Historically, with Georgia's expanding turkey population an average of 3 poults per hen was considered good, however, recent data with a more stable population indicates that productivity threshold of \geq 2.0 poults per hen may be an indicator of good reproductive levels.

Gobblers observed was down in 2010 (653) by 31% from 2009 (952), and down by 13% from the 4-year average (754, 2006-09, Table 7). The hen:gobbler ratio observed in 2010 (2.5) was up 32% from 2009 (1.9), and almost equal to the 4-year average (2.6, Table 8).

Job B. Usable hunt data was supplied by 457 cooperators (above the 5-year average of 440). Of these, 430 came from the permanent cooperator list and 27 from the NWTF list which resulted in a reporting rate (after deleting wrong addresses, deceased, quit hunting, incorrect data collection, etc.) of 37.7% and 3.5% from the permanent and NWTF list cooperators, respectively. These cooperators reported spending a total of 16,327.5 hours hunting (which is above the 5-year average of 16,194.6; Table 9). The average season hunter effort was 10.2 trips (which is less than the 5-year average of 10.8) totaling 35.7 hours (which is less than the 5-year average of 36.8). They reported observing 9,579 turkeys (which is less than the 5-year average of 9,762) and hearing 7,517 gobblers (which is less than the 5-year average of 7,682). The statewide population index of 1.7 was the same as last year (and the 5-year average of 1.7; Table 10). The effort per gobbler heard of 2.2 was 18% worse than last year (1.8 = 2010)and slightly less than the 5-year average of 2.1, which corresponds with the 24.3 hours/turkey harvested being 13% worse than last year (21.2, 2010, but similar to the 5-year average of 24.1; Table 10). The least hunting effort per turkey seen occurred in the Ridge and Valley, Upper and Lower Coastal Plain. The effort per gobbler heard was least in Upper and Lower Coastal Plain and greatest in the Blue Ridge Mountains.

Statewide peak gobbling activity, 2.5 gobblers heard per trip, occurred during the first (March 26-27) weekend (which is equal to the 5-year average for the first week of 2.5). The next highest period recorded 2.1 gobblers heard per trip was the second weekend (April 2-3). This season there were 2 periods with greater than or equal to 2.0 gobblers heard per trip, whereas last year there were 6. For most of the state the

greatest amount of gobbling activity was the first 7 days (Mar 26 – April 1) and the 7day period of April 2- April 8 (the second week of the season; Table 11). Peaks of gobbling by region occurred during the first and sixth weekends (2.2 gobblers heard/hour; March 26-27 and April 30-May 1) for the Ridge and Valley, the third weekend (1.6 gobblers heard/hour; April 9-10) for the Blue Ridge Mountains, the first weekend for the Piedmont (2.4 gobblers heard/hour; March 26-27), first weekend for the Upper Coastal Plain (2.6 gobblers heard/hour; March 26-27), and the first weekend for the Lower Coastal Plain (3.1 gobblers heard/hour; March 26-27).

The statewide gobbler harvest during the first seven days of the season amounted to 30% of the total season harvest (which is just slightly less than the 5-year average of 32 %; Table 12). Peak harvest was generally seen within the first seven days of the season in all parts of the state, except for the Blue Ridge Mountains which peak harvest was from April 4-22 (Tables 13 and 14).

Similar to previous seasons, the greatest number of trips made was during the first seven days of the season (Tables 15 and 16). Only minor variations in hunting effort have occurred over the years.

Hunter success (67.4 %) was equal to last year (2010 = 67.3 %; which corresponds well with the 5-year average 67.1 % [2006-2010]; Table 17) with 308 of 457 hunters reported taking or assisting in taking at least one gobbler. Of the successful hunters, 123 (26.9 %, 5 year average was 25.6 %) took or assisted in taking one bird, 80 (17.5 %, 5 year average was 18.4 %) took or assisted in taking two birds, and 105 (23.0%, 5 year average was 23.1 %; Table 18) took or assisted in taking three birds. Cooperators reported 183 gobblers killed by companions (which is greater than the 5-year average of 156).

The predictive model analysis uses Poults+Hens of the reproductive season during the current year to predict the following years harvest season population index of Hours Hunted/Turkey Seen, where the predictor model (1978-2011) is:

Constant + (Slope *2010 Total Poults+Hens) = 2011 Hours Hunted/Turkey Seen

Therefore:

3.3190 + (-0.00034*4,800) = 1.7 Hours Hunted/Turkey Seen in 2011.

After the production data from 2010 was entered and updated the model, the prediction for the 2011 harvest season was 1.7 hours hunted per turkey seen, which is what was observed. A relatively high inverse correlation r = -0.90 was obtained from the comparison of the new nesting season population index versus the following years harvest season population index.

Jobs A&B

In summary, the 2010 reproductive season was much better than 2009 (tied for worst

on record) and slightly better than the 5-year average. For the 2011 harvest season, hunters took fewer trips, hunted less hours than the 5-year average, and heard fewer gobblers than last year (2010 a record year for hearing gobblers) and the 5-year average. Hunter success and hours/turkey seen were equal to last year and the 5-year average. The hours/turkey harvested was equal to the 5-year average, but less than last year.

Hopefully, the reproduction we experienced in 2010 (while fair) will produce more 2year olds for next spring (2012). This past spring was better than we believed it would be considering hunter success and hours to harvest a turkey. We did predict the time it would take to see a turkey and to hear a gobbler would go up based on last year being a great year for 2-year olds (thanks to the reproduction in 2008) while this past season was going to be tougher due to the terrible reproductive season a majority of the state experienced in 2009. Last year's harvest season experienced 6 periods with at least 2.0 or more gobblers heard per trip, whereas this year hunter's only experienced 2. However, many people still did very well and the percentage of hunters that took or assisted in the harvest of 3+ birds was equal to the 5-year average. All of this reveals how important the hatch is to not only the following year, but also the year after. We've had one good hatch and 2 fair hatches in the past 7 years and last year hunters saw the benefits of the good hatch (2008), this year they saw the results of a bad hatch in 2009, and hopefully next year they will see the results of last' years (2010) fair hatch. One of the most important things to consider when managing turkeys is the effect of harvest and the ability to carry over adult birds into the next year.

Weather extremes, changes in land management and human population growth rates (several GA counties ranked in the top 20 fastest growing nationwide in the past decade) have negatively impacted and likely will continue to negatively impact turkey populations. We are losing turkey habitat and are continuing to suffer regional declines in quality and quantity of turkey habitat leading to an overall lower turkey population than occurred in the previous decade. It is becoming more common to have local population declines in certain areas of the state while others are seeing increasing populations, likely a direct result of changing habitat conditions. For these reasons it is critical that we continue to monitor turkey populations closely into the future.

- E. Recommendations:
 - Job A & B. It is recommended to continue further analyses to determine if there is a better predictor than Total Poults+Hens from what is available within the long-term data.

Table 9. Summary of turkey hunter cooperator data in Georgia, 2011.

¹Roman numerals correspond to physiographic regions as follows:

- I Ridge and Valley
- II Blue Ridge Mountains
- III Piedmont
- IV Upper Coastal Plain
- V Lower Coastal Plain

*includes both gobblers taken and assisted in taking

** less than Regions summed because some hunters hunted in more than one Region
